Milestone1

Chih-Hsuan Chang

Using simulated data modelled on OECD unemployment statistics, this project plans to compare tertiary-educated foreign-born and native-born women across more and less developed regions, and by age at arrival.

Unemployment among Highly Educated Immigrant Women by Destination and Age at Arrival

Introduction

Questions

Immigrants with a university degree are often expected to secure stable positions in the labor market, yet a degree does not guarantee the same outcome across nations. Immigrants may face disadvantages that combine gender and migration status. The strength of these disadvantages may depend on where they settle and on when they arrived. For this research, I focus on highly educated female immigrants and ask: **Does the unemployment rate of tertiary-educated foreign-born women vary by the development level of the destination country and by age at arrival?**

First, **the destination country**: as more developed countries may have more established systems for recognizing foreign qualifications, I expect highly educated foreign-born women to experience lower unemployment in Northern America, Oceania, Western Europe and Northern Europe, which I group as "more developed" regions, than in Latin America, Southern Europe and Eastern Europe, which I group as "less developed" regions. Second, **age at arrival**: women who arrived before age 16 were likely to have integrated and completed much of their schooling in the destination country, so I expect their unemployment to be lower than that of women who arrived at age 16 or older, whose qualifications may have been earned elsewhere and who may have had less time to become familiar with the destination country.

To make the analysis more robust, I also account for general labor market conditions. A low unemployment rate among immigrants may simply reflect a strong labor market that benefits everyone. To separate the two, I also compare each foreign-born group with native-born women of the same region and education level, and examine the gap between them (foreign-born minus

native-born unemployment rate). If immigrant women are better off in more developed regions for reasons beyond general labor market conditions, I expect this gap to be smaller in more developed regions than in less developed ones.

Data

For this project, I plan to using 2023 OECD data on unemployment rates. The data come from the OECD Data Explorer (dataflow DSD_EAG_LSO_EA@DF_LSO_NEAC_UNEMP_MIGR). Each row is a subgroup in one country, defined by sex, age group, education level, place of birth (foreign-born or native-born) and, for the foreign-born, age at arrival (before age 16, or 16 and older). The outcome variable is the unemployment rate, measured as **a percentage of the subgroup's labor force**. I plan to keep women with tertiary education, group countries into regions, and then into "more developed" and "less developed" regions. I compare foreign-born women **by region** and **by age at arrival**, and compare them with native-born women of the same region and education level. I exclude Israel because it is difficult to classify as either a more or less developed region, and I exclude the OECD average because it is not a country.

Limitations

Although the OECD provides detailed data, it does not report immigrants' country of origin. Where immigrants come from may affect whether their educational credentials are recognized in the country of destination, and therefore their unemployment rate. As a result, differences across destination countries in this analysis may partly reflect differences in the origins of their immigrant populations, rather than characteristics of the destination countries themselves.

```

Table 1

Table 1 shows 10 randomly selected rows of the simulated data, where each row is a subgroup in one country, defined by region, place of birth and age at arrival, together with its simulated unemployment rate.

```r
simulated_data |>
  head(10) |>
  select(region, development_group, birth_place, arrival_age, unemployment_rate) |>
  kable(
    col.names = c("Region", "Group", "Place of birth", "Age at arrival", "Unemployment rate
    caption = "Simulated data"
  )
```

Table 1: Simulated data

Region	Group	Place of birth	Age at arrival	Unemployment rate (%)
Northern America	More developed	Foreign-born	Arrived before age 16	8.8
Northern America	More developed	Foreign-born	Arrived at age 16 or older	9.9
Northern America	More developed	Native-born	Not applicable	11.0
Northern America	More developed	Foreign-born	Arrived before age 16	5.6
Northern America	More developed	Foreign-born	Arrived at age 16 or older	5.2
Northern America	More developed	Native-born	Not applicable	6.7
Northern America	More developed	Foreign-born	Arrived before age 16	9.5
Northern America	More developed	Foreign-born	Arrived at age 16 or older	3.0
Northern America	More developed	Native-born	Not applicable	9.2
Northern America	More developed	Foreign-born	Arrived before age 16	3.1

Table2

Table 2 shows the simulated mean gap in unemployment rate between foreign-born and native-born women in more and less developed regions, separately for women who arrived before age 16 and those who arrived at age 16 or older.

```
gap_by_development |>
  kable(
    digits = 2,
    col.names = c("Group",
                  "Arrived before age 16",
                  "Arrived at age 16 or older"),
    align = c("l", "r", "r"),
    caption = "Simulated mean gap in unemployment rate"
  )
```

Table 2: Simulated mean gap in unemployment rate

Group	Arrived before age 16	Arrived at age 16 or older
Less developed	-0.06	0.89
More developed	-0.95	0.67
